• In person from authorized agents and bookstores.

When notifying us of a change in your address, please provide both old and new addresses.

#### Standards of service to the public

Statistics Canada is committed to serving its clients in a prompt, reliable and courteous manner. To this end, the Agency has developed standards of service which its employees observe in serving its clients. To obtain a copy of these service standards, please contact Statistics Canada toll free at 1-800-263-1136. The service standards are also published on www.statcan.ca under "About us" > "Providing services to Canadians."

#### Note of appreciation

Canada owes the success of its statistical system to a long-standing partnership between Statistics Canada, the citizens of Canada, its businesses, governments and other institutions. Accurate and timely statistical information could not be produced without their continued cooperation and goodwill.

### Public Use Microdata File Documentation and User Guide

#### 1. Introduction

This guide was prepared for users of the public use microdata file (PUMF) of the 2013 General Social Survey (GSS) on Social Identity (SI). Its objectives are to provide context and background information, to familiarize users with the content of the survey and to describe procedures and concepts related to collection, processing and methodology.

The 2013 GSS on Social Identity interviewed individuals 15 years and over in Canada's ten provinces<sup>1</sup> and was conducted from June 2013 to March 2014. Interviews were conducted via computer assisted telephone interviewing (CATI) and electronic (Internet) questionnaire (EQ). Data are subject to both sampling and non-sampling errors. These topics are discussed in detail in this guide.

Cycle 27 SI is the third cycle of the GSS to collect data on social engagement and social networks. The previous iteration of the survey was Cycle 22 – Social Networks in 2008 and the first was Cycle 17 – Social Engagement in 2003.

#### 1.1 New to 2013 GSS

There are many new elements to the GSS for 2013. First, the survey frame has changed. Previous GSS cycles were conducted as Random Digit Dialling (RDD) surveys. In 2013, the survey was implemented using the newly redesigned GSS frame, which integrates data from sources of telephone numbers (landline and cellular) available to Statistics Canada and the Address Register (AR) (See section 4.3 for more information). Second, there is a new weighting strategy (See section 7.1) and bootstrap weights have also been changed from mean bootstrap to **standard bootstrap weights** (see Appendix B for more information on how to use standard bootstrap weights).

The 2013 GSS on Social Identity marked the first time a social survey at Statistics Canada offered an Internet option to survey respondents. This new approach to data collection was in recognition of the success of online data collection with the Census, combined with the need to adapt to the changing use of technology and the ever present demands on Canadians' time. By having both telephone and Internet modes of data collection, the 2013 GSS offered survey respondents greater flexibility and convenience in providing key and vital information to Statistics Canada (see section 5).

Finally, two federal government departments asked Statistics Canada to add an oversample of immigrants and youth to the 2013 GSS to allow for a more sophisticated analysis of these groups. In order to achieve this, the oversample was allocated at different desired levels (See section 4.2.2).

It is important to point out that any significant change in survey methodology (as outlined above) can affect the comparability of the data over time. It is impossible to determine with certainty whether, and to what extent, differences in a variable are attributable to an actual change in the population or to changes in the survey methodology. Consequently, at every stage of processing, verification and dissemination, considerable effort was made to

<sup>&</sup>lt;sup>1</sup>The survey excludes residents of the Yukon, Northwest Territories and Nunavut, as well as full-time residents of institutions.

#### Public Use Microdata File Documentation and User Guide

produce data that are as precise in their level of detail, and to ensure that the published estimates are of good quality in keeping with Statistics Canada standards.

#### 2. Objectives of the General Social Survey

The GSS program, established in 1985, conducts surveys across the 10 provinces. The GSS is recognized for its regular collection of cross-sectional data that allows for trend analysis, and its capacity to test and develop new concepts that address current and emerging issues.

The two primary objectives of the General Social Survey are:

- a) To gather data on social trends in order to monitor changes in the living conditions and well-being of Canadians over time; and
- b) To provide immediate information on specific social policy issues of current or emerging interest.

To meet these objectives, the data collected by the GSS are made up of two components: classification and core content. Classification content (such as age, sex, education, income) helps to delineate population groups for use in the analysis of core data. Core content is designed to measure changes in society related to living conditions and well-being and to supply data to inform specific policy issues.

#### 3. Content of the 2013 GSS on Social Identity

#### Introduction

This preliminary section is administered for the purposes of introducing the survey and selecting a respondent. A household roster is created, which collects key demographic information on each member of the household, including age, sex, marital status and relationships to other household members. In addition to the technical utility of this section for establishing the flow of subsequent questions, the data collected here are used to derive core family structure information for Canadian households.

#### Section 1 - Social Networks

The first content section of the survey aims to shed light on the contacts the respondent has with his/her family, friends and acquaintances. Frequency of face-to-face contact as well as telephone, text and email contact is measured in this section. Internet use, characteristics of friends and interaction with new people is also covered in this section of the survey.

#### Section 2 - Civic Participation

This section focuses on the respondent's participation in groups and organizations, including the socio-demographics of people met through those groups and organizations. The section also includes questions on engagement with politics, voting (federal, provincial and municipal) and the various modes of media used to follow news and current affairs.

#### Section 3 - Pride, Symbols and Values

This section contains content that is new to GSS and relates to the social identity of Canadians. Questions around self-rated knowledge of Canadian history, pride in Canadian achievements as well as appreciation and importance of national symbols are asked in this

### Public Use Microdata File Documentation and User Guide

section. The extent to which Canadians share similar values (human rights, gender equality, cultural diversity, etc.) is also measured in this section.

#### Section 4: Main Activity of Respondent

Information in this section is collected about the respondent's main activity during the past 12 months, including the number of weeks worked, number of hours worked in a typical week, type of work schedule and satisfaction with work-life balance. The section also includes questions on the respondent's education<sup>2</sup> as well as main activity and education of his/her spouse/partner.

#### Section 5: Birthplace and Ethnic Origin

Information in this section is collected about the respondent's place of birth as well as that of their mother, father and spouse/partner. Respondents are also asked which country (up to 3) they are a citizen of. Additional questions are asked of respondents not born in Canada to determine when they first arrived in Canada, and when and how they became landed immigrants (if applicable). Ethnic origin, Aboriginal identity and visible minority status are also determined in this section for both the respondent and their spouse/partner.

#### Section 6: Sense of Belonging and Trust

This section includes the respondent's sense of belonging to their local community, city, province, and to Canada. Respondents born outside of Canada are also asked about their sense of belonging to their country of origin. For the first time in GSS, respondents are also asked about their sense of belonging to people with the same ethnic or cultural background and language.

Trust is another component of the section as the respondents are asked about their trust in people generally speaking, or; in their family, neighbourhood, school or work, strangers and people who speak a different language. Respondents are also asked the perceived likelihood that their wallet would be returned if found by someone who lives close by, a stranger and a police officer. Confidence in various institutions (including the police, justice system, schools, Federal Parliament, etc.) are also included in this section as well as experiences of discrimination.

#### Section 7: Well-being

This section covers the respondent's self-rated health, mental health and life satisfaction. These are all considered important factors in assessing the well-being of Canadians.

#### Section 8: Classification

This section provides a variety of socio-demographic measures—many of which are repeated each year in the General Social Survey in order to support the analysis of Canadian families and individuals. This cycle of the GSS includes housing characteristics of the respondent, religion, language, sexual orientation, and personal and household income.

<sup>&</sup>lt;sup>2</sup> Respondents that were part of the immigrant oversample are asked an extended set of education questions which included the year and country where they obtained their highest degree or certificate.

### Public Use Microdata File Documentation and User Guide

#### 4. Survey and Sample Design

Data for 2013 General Social Survey (GSS) on Social Identity (SI) was collected from June 2013 to March 2014. The target population is described in section 4.1, the stratification of the sampling plan in section 4.2, the frame in 4.3 and the sampling strategy in 4.4. Finally, the sample size and allocation are described in section 4.5.

#### 4.1 Target population

The target population for the survey included all persons 15 years of age and older in Canada, excluding:

- 1. Residents of the Yukon, Northwest Territories, and Nunavut;
- 2. Full-time residents of institutions.

#### 4.2 Stratification

#### 4.2.1 Stratification for the regular sample

In order to carry out sampling, each of the ten provinces were divided into strata (i.e. geographic areas). Many of the Census Metropolitan Areas (CMAs) were each considered separate strata. This was the case for St. John's, Halifax, Saint John, Montreal, Quebec City, Toronto, Ottawa, Hamilton, Winnipeg, Regina, Saskatoon, Calgary, Edmonton and Vancouver.

All CMAs not on this list are located in Quebec, Ontario and British Columbia, with the exception of Moncton. Three more strata were formed by grouping the remaining CMAs (except Moncton) in each of Quebec, Ontario and British Columbia. Finally, the non-CMA areas of each of the ten provinces were also grouped to form ten more strata, for a total of 27 strata. Moncton was added to the non-CMA stratum for New Brunswick.

#### 4.2.2 Stratification for the oversample of immigrants and youth

Only specific geographies were targeted for the oversample of immigrants and youth.

For the oversample of immigrants, only the Census Metropolitan Areas of Montreal, Toronto, Winnipeg, Calgary, Edmonton and Vancouver were considered as separate strata. Another stratum was formed by grouping the provinces of Newfoundland and Labrador, Prince Edward Island, Nova Scotia and New Brunswick. The province of Saskatchewan also formed a stratum on its own. Lastly, all the remaining geographic areas of the ten provinces not covered previously were grouped together to form the last stratum.

For the oversample of youth, only the Census Metropolitan Areas of Halifax, Montreal, Ottawa, Toronto, Winnipeg, Calgary, Edmonton and Vancouver were covered by the frame and considered as separate strata. Also, for each geographic area, two strata were formed: one with the households including at least one immigrant between the age of 15 and 24 and one with the households including at least one non-immigrant between the age of 15 and 24.

#### 4.3 Frame

The survey frame was created using two different components:

1. Lists of telephone numbers in use (both landline and cellular) available to Statistics Canada from various sources (Telephone companies, Census of population, etc.);

2. The Address Register (AR): List of all dwellings within the ten provinces.

The Address Register (AR) was used to group together all telephone numbers associated with the same valid address. About 88% of telephone numbers available were linked to the AR. The records resulting from this linkage could possess more than one telephone number (grouped by the address). The other 12% of telephone numbers not linked to the AR were also included in the frame and each of them constitutes a single record. The combination of those two components results in the survey frame. The rationale for using all the telephone numbers (linked and not linked) was to ensure a good coverage of all households with telephone numbers.

When more than one telephone number was attached to a record, they were sorted by source and by type of telephone number (landline telephone numbers first and cellular telephone numbers last). The first telephone number was considered the best telephone number available to reach the household.

Separate frames were created for the oversample of immigrants and for the oversample of youth. For the oversample of immigrants, the survey frame created for the regular sample was used first. A flag from an administrative source identifying the households with at least one immigrant was then added and only households flagged as having at least one immigrant were kept on the frame.

The same principle was used to create the frame for the oversample of youth, but in this case, the flag identified households with at least one person between the age of 15 and 24 years old. This frame was also stratified to separate households with at least one immigrant between the age of 15 and 24 years old from the households with at least one non-immigrant (born in Canada) between the ages of 15 and 24 years old.

Please note that for the remaining sections of this document, the word "record" will refer to the grouping of telephone numbers that consists of our sampling unit on the survey frame.

#### 4.4 Sampling strategy

In each frame, each record was assigned to a stratum within its province. A simple random sample without replacement of records was next selected in each stratum.

Coverage of the 2013 GSS on Social Identity targeted population by the survey frame is estimated to be more than 88% complete. All respondents in the ten provinces were

### Public Use Microdata File Documentation and User Guide

interviewed by telephone as the first point of contact<sup>3</sup>. Households without telephones were therefore excluded. In 2013, the proportion of households without any phone service was estimated at 1% (Residential Telephone Services Survey (RTSS), 2013). The remaining 11% of under-coverage are households possessing at least one telephone number with the majority of them having only cellular telephone numbers. Survey estimates were adjusted (weighted) to represent all persons in the target population, including those not covered by the survey frame.

For the 2013 GSS SI, 81.1% of the telephone numbers dialed reached eligible households. An attempt was then made to conduct an interview with one randomly selected person from each household.

It should be noted that the eligibility criteria were different for each of the three samples. For the regular sample, a household was eligible if it included at least one person 15 years of age or older. For the oversample of immigrants, a household was eligible if it included at least one person 15 years of age or older born outside of Canada. Lastly, for the oversample of youth, a household was eligible if it included at least one person between the age of 15 and 24 years old.

During collection, for the households not meeting the eligibility criteria, the interviews were terminated after an initial set of questions that established whether or not they met the criteria. For the oversample cases, an extra question was asked to determine if each person in the household was born in Canada or not.

#### 4.5 Sample size and allocation

The target sample size (i.e. the number of respondents) for Cycle 27 SI was 31,973, while the actual number of respondents was 27,695. Some GSS respondents were removed from the PUMF for confidentiality reasons. GSS Cycle 27 PUMF contains questionnaire responses and associated information from 27,534 respondents.

#### 5. Collection

Computer assisted telephone interviewing (CATI) and electronic questionnaire (EQ) surveys were used to collect data for the GSS on Social Identity. Respondents were interviewed in the official language of their choice. Proxy interviews were not permitted.

All interviewing took place using centralized telephone facilities in four of Statistics Canada's regional offices, with calls being made from approximately 09:00 to 21:30 on Monday to Friday. Interviewing was also usually scheduled from 9:00 to 17:00 on Saturdays and on Sunday afternoons and evenings (13:30 to 21:00). The four regional offices were: Halifax, Sherbrooke, Winnipeg and Edmonton. Interviewers were trained by Statistics Canada staff in telephone interviewing techniques using CATI, survey concepts and procedures. The majority of interviewers had previous experience interviewing for the GSS.

<sup>&</sup>lt;sup>3</sup> Households were first contacted by telephone and an individual aged 15 years or older was randomly selected to respond to the survey. This individual was then offered to continue the interview by phone or to complete the survey over the Internet (EQ).

In terms of EQ, respondents who accepted the offer to complete the survey online (EQ), provided their email address to finish the CATI portion of the interview and were then sent an email invitation the next business day. Respondents could then access the survey using the link and access code provided in the invitation email<sup>4</sup>. Reminder emails were sent every 7 days (up to a maximum of 3) until the respondent submitted the EQ survey or the online collection portal closed<sup>5</sup>. Respondents, who did not complete the survey online after the final email reminder (or prior to the close of the EQ portal) were transferred back to the CATI environment for telephone follow up.

Data for the GSS SI were collected from June 2013 to March 2014. The sample was initially divided into three non-overlapping waves of collection, each lasting two months. In an effort by Statistics Canada to improve the overall survey response rate, an additional 4th wave of collection began on January 2<sup>nd</sup> 2014 and concluded on March 31<sup>st</sup> 2014. This 4th wave included follow-up of non-response for some cases from Waves 1 to 3 as well as additional new cases<sup>6</sup>.

Survey manuals are not included in this documentation package but can be made available by contacting Statistics Canada (see Section 9).

#### 6. Processing

#### 6.1 Data capture

Using CATI, responses to survey questions were entered directly into computers in the regional offices as the interview progressed. EQ surveys were accessed by respondents using the link in their invitation (or reminder) email. All information collected (in both collection CATI and EQ) was transmitted electronically to Ottawa and then merged into one data file for processing.

#### 6.2 Coding

Some questions allowed write-in responses. These responses were coded into existing categories (where a match was possible), grouped into new categories, or left in "other – specify" (if a match with an existing category was not possible or frequencies were too small to create a new category). Where possible the coding followed the standard classification systems as used by the GSS, Statistics Canada's harmonized content program and the Census of Population.

#### 6.3 Edit and imputation

All survey records were subjected to computer edits throughout the course of the interview. The survey application identified out of range values as they were entered. As a result, the

<sup>&</sup>lt;sup>4</sup> The EQ application allowed respondents the ability to start the survey and save their responses in order to login (using a password) and complete the survey at a later time if required.

<sup>&</sup>lt;sup>5</sup> The online collection (EQ) portal closed 2 weeks prior to the end of each collection period (or wave) in order to allow sufficient time for telephone follow up with respondents who did not complete the survey by Internet.
<sup>6</sup> The 4<sup>th</sup> wave of collection primarily focused on non-response cases from the previous 3 waves (including 4,000 additional new cases) in an effort to improve overall global response rates. For this reason, the decision was made to use telephone (CATI) as the only mode of collection for this 4<sup>th</sup> wave.

interviewer (in CATI) or the respondent (in EQ) could immediately correct the information provided to resolve the issue. If the interviewer (or the respondent) was unable to correctly resolve the detected errors, it was possible to bypass the edit to continue the survey and the data was reviewed later by head office. All interviewer comments from the CATI system were reviewed and taken into account in head office editing.

Head office edits performed the same checks as the CATI and EQ systems as well as more detailed edits. Due to the nature of the survey, imputation was not appropriate for most items. Records with missing or incorrect information were, in a small number of cases, completed or corrected deterministically from other information on the questionnaire. The flow editing carried out by head office followed a "top down" strategy, in that whether or not a given question was considered "on path" was based on the response codes to the previous questions. If the response codes to the previous questions indicated that the current question was "on path", the responses, if any, to the current question were retained, though "don't know" was recoded as 7 (97 or 997, etc.) and refusals as 8 (98 or 998, etc.); if, however, a response was missing to the current question, it was coded as "Not Stated", i.e. 9 (99 or 999, etc.). If the response codes to the previous questions indicated that the current question was "off path" because the respondent was clearly identified as belonging to a subpopulation for which the current question was inappropriate or not of interest, the current question was coded as "Valid Skip", i.e. 6 (96 or 996, etc.).

Non-response was not permitted for those items required for weighting. Values were imputed in the rare cases where the sex of the respondent was missing. The imputation was based on a detailed examination of the data and the consideration of any useful data such as the age and sex of other household members, and the interviewer's comments.

#### 6.4 Creation of combined and derived variables

A number of variables on the file were derived from information collected on the questionnaires. In some cases, the derived variables are straightforward and involve collapsing of categories. In other cases, two or more variables were combined to create a new variable. The data dictionary identifies which variables are derived and the nature of their derivation.

#### 7. Estimation

When a probability sample is used, as is the case for the GSS, the principle behind estimation is that each person selected in the sample represents (in addition to himself or herself) several other persons not in the sample. For example, in a simple random sample of 2% of a population size of 1000, each person in the sample represents 50 persons in the population. The number of persons represented by a given person in the sample is usually known as the weight or weighting factor of the sampled person.

GSS Cycle 27 SI estimates can be produced from the PUMF. This file contains questionnaire responses and associated information from 27,534 respondents<sup>7</sup>.

<sup>&</sup>lt;sup>7</sup> As mentioned in section 4.5, the actual number of GSS respondents was 27,695. Some GSS respondents were removed from the PUMF for confidentiality reasons.

A weighting factor is made available to analysts in the PUMF.

WGHT\_PER: This is the basic weighting factor for analysis at the person level, i.e. to calculate estimates of the number of persons (non-institutionalized and aged 15 or over) having one or several given characteristics. WGHT\_PER should be used for all person-level estimates. For example, to estimate the number of persons who say their health is excellent, the value of WGHT\_PER is summed over all records with this characteristic.

#### 7.1 Weighting of persons

We view each cycle of the GSS as being comprised of a number of independent surveys - one per wave of collection. Wherever possible, therefore, we weight each wave independently so that the data collected for each contributes to the estimates in proportion to the Canadian population at that time. Since the number of additional cases in the 4th wave was insufficient to treat the wave on its own, the records were grouped with the 3rd wave at certain stages of the weighting process.

As mentioned previously, the records on the survey frames are groups of telephone numbers. A simple random sample of those records was selected in each stratum. Therefore, each record within a stratum has an equal probability of selection.

This probability is equal to:

Number of records sampled in the stratumNumber of records in the stratum in the specific survey frame

#### 1) Initial weight calculation

Certain households in the survey frame had a probability of being reached through more than one record. This was possible since groupings of telephone numbers were subject to error.

As mentioned previously, telephone numbers belonging to the same valid address were grouped together on the survey frame. However, for a few cases, the grouping of those telephone numbers might be erroneous (i.e. all the telephone numbers grouped together do not belong to the same household). In addition, the remaining 12% of telephone numbers that could not be linked to addresses were also included in the frame. It is possible that some of those telephone numbers could reach households already covered by the 88% of telephone numbers linked to addresses.

As a result, a series of questions were added to the survey to establish the prevalence of these situations. Several adjustments were made to the initial probability of selection to account for the fact that such households had a higher probability of being selected (i.e. they could be contacted through more than one group of telephone numbers). Therefore, the initial weight is the inverse of this adjusted probability of selection.

#### 2) Removal of out-of-scope records

Telephone numbers associated with businesses, institutions or other out-of-scope dwellings, as well as numbers not in service or any other non-working numbers are all examples of out-of-scope telephone numbers for this survey. Records with all telephone numbers out-of-scope are simply removed from the process, leaving only in-scope records in the sample. These in-scope records keep the same initial weight as described in the previous step.

#### 3) Two-stage non-response adjustment

Weights for responding households were adjusted to represent non-responding households. This was done independently within each stratum-wave group.

Non-responding households were grouped into two types; those with some auxiliary information available (i.e. a complete roster of household members) and those with no auxiliary information.

This non-response adjustment was done in two stages. In the first stage, adjustment was made for complete non-response (i.e., households for which no auxiliary information was available). In the second stage, adjustment was made for partial non-response. These households had some auxiliary information which was used to model propensity to respond. The combination of these two adjustments is referred to as Factor 1.

Non-responding households were then dropped.

#### 4) Person weight calculation

A person weight was then calculated for the respondent by multiplying the household weight by the number of persons in the household who were eligible to be selected for the survey.

As previously mentioned, eligibility criteria are different for the regular sample, for the oversample of immigrants and for the oversample of youth. For the regular sample, the number of eligible household members is the number of persons 15 years of age or older. For the oversample of immigrants, the number of eligible household members is the number of persons 15 years of age or older that were not born in Canada. Lastly, for the oversample of youth, the number of eligible household members is the number of persons between the age of 15 and 24 (born in or outside of Canada depending on the stratum).

This step produces a person weight = Initial Household Weight x Factor 1 x Number of eligible household members.

#### 5) Integration of the oversample of immigrants and youth with the regular sample

So far, steps 1, 2 and 3 were done independently for each sample (the regular sample, the oversample of immigrants and the oversample of youth). This means, up to this point, a series of weights exist for each sample and each series represents the population covered by its survey frame.

We want to combine all the samples together to obtain only one series of weights, which will represent the population of Canadians in the ten provinces aged 15 years or older.

To combine the three samples, an adjustment, Factor 2, is calculated using the proportion of respondents in each sample by category of respondents. The resulting weight is equal to: Initial Household Weight x Factor 1 x Number of eligible household members x Factor 2.

#### 6) Adjustment of person weights to external totals

The person weights were adjusted several times using a raking ratio procedure. This procedure ensures that, based on the survey's total sample, estimates produced that should match certain external reference totals do indeed match them. Two sets of external references were used for this survey, both of them population totals: for stratum (geographic) by wave, and for age-sex groups by province.

It should be noted that persons living in households without telephone service (or telephone service not covered by the frame) are included in the external references even though such persons were not sampled.

#### 6a) Stratum - Wave Adjustment

An adjustment was made to the person weights on records within each stratum (geographic) per wave in order to make population estimates consistent with the corresponding projected population counts. This was done by multiplying the person weight for each record within the stratum by the following ratio:

Projected population count for the stratum – wave Sum of the person weights for the stratum – wave

When sample sizes were small (< 15), data for consecutive waves in the same stratum were combined before this adjustment was made.

#### 6b) Province - age - sex adjustment

The next weighting step was to adjust the weights to agree with projected province-age-sex population distributions.

Projected population counts were obtained for males and females within the following sixteen age groups:

15-19	20-24	25-29	30-34
35-39	40-44	45-49	50-54
55-59	60-64	65-69	70-74
75-79	80-84	85-89	90 +

For each of the resulting classifications the person weights for records within the classification were adjusted by multiplying by the following ratio:

Projected province – age – sex group population count Sum of the province – age – sex group person weights

When sample sizes were small, adjacent age group data for the same province and sex were combined before this adjustment was made.

#### 6c) Raking ratio adjustments

As previously stated in 6), the weights of each respondent were adjusted several times using a raking ratio procedure to ensure that estimates produced for Stratum-Wave and Province-Age-Sex totals agree with the external reference totals. This adjustment was made by repeating steps 6a) and 6b) of the weighting procedures until each repetition of the step made a minimal adjustment to the weights.

#### 7) Final person weight

The weight produced at the end of step 6) is the final person weight WGHT\_PER placed on the main data file.

#### 7.2 Weighting policy

Users are cautioned against releasing unweighted tables or performing any analysis based on unweighted survey results. As was discussed in Section 7.1, there were several weight adjustments performed that were dependent on the province, stratum, age and sex of the respondent. Sampling rates as well as non-response rates varied significantly from province to province, and non-response rates varied with demographic characteristics. For example, non-respondents were often more likely to be males and more likely to be younger. In the responding sample, 2.4% were males between the ages of 20 and 24, while in the overall population, approximately 4.3% were males between 20 and 24. Therefore, it is clear that unweighted sample counts cannot be considered representative of the survey target population.

The total number of households in the sample's scope was estimated at 57,535. Among these resolved households, 27,695 usable responses were obtained, which gives an overall response rate of 48.1% (48.9% for the regular sample, 45.0% for the oversample of immigrants and 48.1% for the oversample of youth). The distribution of the non-response and response categories is presented in the following table:

	Regı Sam	ılar ple	Oversa of immi	ample grants	Oversan you	nple of th	Total sa	mple
Source	Number	%	Number	%	Number	%	Number	%
1.Household non-response*	15,661	36.1	3,928	37.7	1,208	32.2	20,797	36.1
2.Refusal by selected person	2,848	6.6	538	5.2	279	7.4	3,665	6.4
3.Other non- response by person	3,652	8.4	1,270	12.2	456	12.2	5,378	9.3
4. Response	21,200	48.9	4,692	45.0	1,803	48.1	27,695	48.1
Total Households	43,361	100	10,428	100	3,746	100	57,535	100

### Public Use Microdata File Documentation and User Guide

In all, the number of non-response cases is estimated at 29,840 cases. Categories 2 and 3 show non-response occurring after the respondent was selected in households. The "other non-response" category (3) includes cases where no response could be obtained because of language difficulties or other problems.

As mentioned in section 4.5, 161 GSS respondents were removed from the PUMF for confidentiality reasons. The person weights for the 27,534 respondents in the PUMF were adjusted accordingly.

#### 7.3 Types of estimates

Two types of 'simple' estimates are possible from the results of the General Social Survey. These are qualitative estimates (estimates of counts or proportions of people possessing certain qualities or characteristics) and quantitative estimates involving quantities or averages. More complex estimation and analyses are covered in sections 7.4 and 7.5.

#### 7.3.1 Qualitative estimates

The target population for the GSS was non-institutionalized persons aged 15 and older, living in the ten provinces. Qualitative estimates are estimates of the number or proportion of this target population possessing certain characteristics. The number of people (6,738,345) who describe their state of health as excellent (SRH\_Q110 = 1) is an example of this kind of estimate. These estimates are readily obtained by summing the person weights (WGHT\_PER) of the records possessing the characteristic of interest. This estimate does not, however, adjust for non-response to the question in any way.

If we make the assumption that those who either refused to answer the question or who responded 'Don't know' have the same distribution as those who responded, then an

<sup>\*</sup> For the regular sample, the number of household non-response is exact. However, for the oversample of immigrants and the oversample of youth, this number represents the number of non-response households that we estimate to be eligible. This estimate was calculated using the eligible rate observed within the resolved households (i.e. the households that were determined as eligible). Since the composition of the household could not be determined for those 5,136 cases, some of them in fact may not be eligible.

adjusted estimate can be made. To do this, the proportion of the target population with this characteristic is estimated excluding respondents with a 'Not stated' or 'Don't know' answer to question SRH\_Q110 and calculating the ratio of the total of the weights of those respondents who answered that their state of health was 'Excellent' (SRH\_Q110=1) to that of all respondents who answered the question (SRH\_Q110=1, 2, 3, 4, or 5). This proportion is then multiplied by the size of the target population to produce the final estimate (it should be noted that this adjustment does not have to be done, but it can be if needed):

$$6,835,155 = 29,131,913 \times \frac{6,738,345}{28,719,303}$$

29,131,913 is the estimated number of persons aged 15 and over in the population (target population). 28,719,303 is the sum of the weights of all respondents who answered question SRH\_Q110 (i.e. SRH\_Q110 = 1,2,3,4 or 5). When the proportion of responses that are 'Don't know' or 'Refused' are high, the differences between the two estimates will be large.

#### 7.3.2 Quantitative estimates

Some variables on the GSS PUMF are quantitative in nature (e.g. age, number of weeks worked in the past 12 months). From these variables, it is possible to obtain such estimates as the average number of weeks worked in the past 12 months. These quantitative estimates are of the following ratio form:

Estimate (average) = X / Y

The numerator (*X*) is a quantitative estimate of the total of the variable of interest (for example, the number of weeks worked in the past 12 months) for a given sub-population (for example, males who worked in the past 12 months). In this example, *X* would be calculated by multiplying the person weight (WGHT\_PER) by the variable of interest (WET\_Q110) when it is known,  $1 \le WET_Q110 \le 52$ , (i.e. not equal to '96','97','98' or '99'), and summing this product over all records for males who worked i.e. SEX=1 and ( $1 \le WET_Q110 \le 52$ ), which yields 483,692,298.

The denominator (*Y*) is the qualitative estimate of the number of persons within that subpopulation (males who worked in the past 12 months). In this example, *Y* would be calculated by summing the person weight (WGHT\_PER) over all male respondents with  $1 \le WET_Q110 \le 52$ , yielding 11,025,725.

The two estimates *X* and *Y* are derived independently and then divided to provide the quantitative estimate. The average number of weeks is then calculated to be:

$$\frac{483,692,298}{11,025,725} = 43.87$$

#### 7.4 Guidelines for analysis

As detailed in Section 4 of this document, the GSS respondents do not form a simple random sample of the target population. Instead, the survey had a complex design, with stratification and multiple stages of selection, and unequal probabilities of selection of respondents. Using data from such complex surveys presents analytical challenges because the survey design and the selection probabilities affect the estimation and variance calculation procedures that should be used.

The GSS used a stratified design, with significant differences in sampling fractions between strata. Thus, some areas were over-represented in the sample (relative to their populations) while some other areas were relatively under-represented; this means that the unweighted sample was not representative of the target population, even if there was no non-response. Non-response rates may vary by demographic group, making the unweighted sample even less representative.

The survey weights must be used when producing estimates or performing analyses in order to account as much as possible for the over- and under-representation of geographic areas, age-sex groups and months of the year in the unweighted file. While many analysis procedures found in statistical packages allow weights to be used, the meaning or definition of the weight in these procedures often differs from that which is appropriate in a sample survey framework, with the result that while in many cases the estimates produced by the packages are correct, the variances that are calculated are almost meaningless.

For many analysis techniques (for example linear regression, logistic regression, estimation of rates and proportions, and analysis of variance), a method exists which can make the variances calculated by the standard packages more meaningful. If the weights on the data, or on the subset of the data that is of interest, are rescaled so that the average weight is one (1), then the variances produced by the standard packages will be more reasonable; they still will not take into account the stratification and clustering of the sample's design, but they will take into account the unequal probabilities of selection. This rescaling can be accomplished by dividing each weight by the overall average weight before the analysis is conducted. Section 8 describes sampling variability and data reliability in more detail.

#### 7.5 Methods of estimation and interpretation of estimates

#### 7.5.1 Estimating numbers of persons by using WGHT\_PER

As previously mentioned, a basic person weight has been assigned to each sampled individual and, as described in Section 7.1, these weights have been adjusted to reflect the age and sex composition of the various provincial populations as estimated by Statistics Canada for each month covered by Cycle 27 SI.

$$\sum_{i=1}^{27,534} \text{WGHT}_{\text{PER}_i} = 29,131,913^1$$

<sup>1</sup> Estimate of the number of persons aged 15 and over in the population.

### Public Use Microdata File Documentation and User Guide

In general, when an estimate is based on the unit of observation being the person, the WGHT\_PER should be used. Examples of this are the average number of weeks worked by persons aged 25 to 29 years old, and the number of people aged 25 to 44 years old who have attended school as their main activity during the last 12 months. For this example, an estimate would be calculated as follows: WGHT\_PER would be summed up for all records on the data file with 2 <= AGEGR10 <= 3 and MAR\_110 = 3, providing an estimate of 561,126 persons aged 25 to 44 years old who have attended school as their main activity during the last 12 months.

#### 8. Release guidelines and data reliability

It is important for users to become familiar with the contents of this section before publishing or otherwise releasing any estimates derived from the General Social Survey Social Identity PUMF.

This section of the documentation provides guidelines to be followed by users. With the aid of these guidelines, users of the PUMF should be able to produce figures consistent with those produced by Statistics Canada and in conformance with the established guidelines for rounding and release. The guidelines can be broken into four broad sections: Minimum Sample Sizes for Estimates; Sampling Variability Policy; Sampling Variability Estimation; and Rounding Policy.

#### 8.1 Minimum sample size for estimates

Users should determine the number of records on the PUMF which contribute to the calculation of a given estimate. This number should be at least 15. When the number of contributors to the weighted estimate is less than 15, the weighted estimate should generally not be released regardless of the value of the Approximate Coefficient of Variation. If it is released, it should be with great caution and the insufficient number of contributors associated with the estimate should be prominently noted.

#### 8.2 Sampling variability guidelines

The estimates derived from this survey are based on a sample of persons. Somewhat different figures might have been obtained if a complete census had been taken using the same questionnaire, interviewers, supervisors, processing methods, etc. as those actually used. The difference between the estimates obtained from the sample and the results from a complete count taken under similar conditions is called the sampling error of the estimate.

Errors which are not related to sampling may occur at almost every phase of a survey operation. Interviewers may misunderstand instructions, respondents may make errors in answering questions, the answers may be incorrectly entered into the CATI or EQ systems, and errors may be introduced in the processing and tabulation of the data. These are all examples of non-sampling errors.

Over a large number of observations, randomly occurring errors will have little effect on estimates derived from the survey. However, errors occurring systematically will contribute to biases in the survey estimates. Considerable time and effort was made to reduce non-

Public Use Microdata File Documentation and User Guide

sampling errors in the survey. Quality assurance measures were used at each step of the data collection and processing cycle to monitor the quality of the data. These measures included the use of highly skilled interviewers, extensive training of interviewers with respect to the survey procedures and questionnaire, observation of interviewers to detect problems of questionnaire design or misunderstanding of instructions, and coding and edit quality checks to verify the processing logic.

#### 8.2.1 Non-sampling errors

A major source of non-sampling errors in surveys is the effect of non-response on the survey results. The extent of non-response varies from partial non-response (failure to answer one or a few questions) to total non-response. Total non-response occurred because either the interviewer was unable to contact the respondent, no member of the household was able to provide the information (perhaps due to a language problem), or the respondent refused to participate in the survey. Total non-response was handled by adjusting the weight of households who responded to the survey to compensate for those who did not respond.

In most cases, partial non-response to the survey occurred when the respondent did not understand or misinterpreted a question, refused to answer a question, or could not recall the requested information.

#### 8.2.2 Sampling errors

Since it is an unavoidable fact that estimates from a sample survey are subject to sampling error, sound statistical practice calls for researchers to provide users with some indication of the magnitude of this sampling error.

Although the exact sampling error of the estimate, as defined above, cannot be measured from sample results alone, it is possible to estimate a statistical measure of sampling error, the standard error, from the sample data. Using the standard error, confidence intervals for estimates (ignoring the effects of non-sampling error) may be obtained under the assumption that the estimates are normally distributed about the true population value. The chances are about 68 out of 100 that the difference between a sample estimate and the true population value would be less than one standard error, about 95 out of 100 that the difference would be less than two standard errors, and virtually certain that the differences would be less than three standard errors.

Since the absolute size of the sampling error of an estimate is often less important than its relative size (relative to the estimate itself) the standard error is not always the best measure of sampling error. For example, a standard error of 10 for an estimate of 20 would generally be taken as indicating that the estimate is a poor one, while the same standard error for an estimate of 1,000 would generally indicate a good estimate. For this reason the size of the sampling error is often expressed relative to the size of the estimate, as the coefficient of variation (CV). The coefficient of variation of an estimate is obtained by dividing the standard error of the estimate by the estimate itself, and the resulting fraction is usually expressed as a percentage. In the above example, the first estimate has a CV of 50% (10/20), while the second has a CV of 1% (10/1,000).

The choice between using the standard error or the CV as a measure of sampling variability is one the user should make based on his/her specific analysis. Guidelines for publishing estimates using the CV are given in the next section.

With enough observations, the user can proceed to calculating variances and coefficients of variation using the bootstrap weights provided with the data (see Section 8.2.3 for guidelines to follow when using coefficients of variation and Section 8.3 for more details on the appropriate software to use for bootstrap weights).

#### 8.2.3 Guidelines for release of estimates

When considering releasing *and/or* publishing an estimate from the PUMF, users should consult the table below and follow the guideline that matches the coefficient of variation of the estimate.

Type of Estimate	Coefficient of Variation	Policy Statement
1.With Moderate Sampling Variability	0.0% to 16.5%	Estimates can be considered for general unrestricted release. No special notation is required.
2. With High Sampling Variability	16.6% to 33.3%	Estimates can be considered for general unrestricted release but should be accompanied by a warning cautioning users of the high sampling variability associated with the estimates.
3. With Very High Sampling Variability	33.4% or over	Estimates should generally not be released, but when they are it should be with great caution and the very high sampling variability associated with the estimate should be prominently noted.

#### 8.3 Variance estimation using bootstrap weights

#### 8.3.1 Bootstrap method for variance estimation

In order to determine the quality of the estimate and to calculate the CV, the standard deviation must be calculated. Confidence intervals also require the standard deviation of the estimate. The GSS uses a multi-stage survey design and calibration, which means that there is no simple formula that can be used to calculate variance estimates. Therefore, an approximate method is needed. The bootstrap method is used because the sample design and calibration needs to be taken into account when calculating variance estimates. With the use of available software to compute variances with the help of bootstrap weights (discussed in the next subsection), the method is fairly easy for users.

This technique involves dividing the records on the microdata file into subgroups (or replicates) and determining the variation in the estimates from replicate to replicate. The replicates are formed by selecting independently within each stratum a simple random sample with replacement of (n-1) of the n units in the sample. Note that since the selection is with replacement, a unit may be chosen more than once. A bootstrap weight based on the bootstrap sample is calculated for each sample unit in the stratum. This process (selecting simple random samples, recalculating weights for each stratum) is repeated B times, where B is large, yielding B different initial bootstrap weights. The GSS typically uses B=500, to produce 500 bootstrap weights.

These weights are then adjusted according to the same weighting process as the regular person weights: non-response adjustment, calibration and so on. The end result is 500 final bootstrap weights for each unit in the sample. The variation among the 500 possible estimates based on the 500 bootstrap weights is related to the variance of the estimator based on the regular weights and can be used to estimate it.

#### 8.3.2 Bootvar program for variance estimation

Statistics Canada has developed a program that can perform Bootstrap variance estimation: the Bootvar program.

The Bootvar program is available in SAS as well as SPSS format. It is made up of macros that compute variances for totals, ratios, differences between ratios and for linear and logistic regression.

Tips for using the GSS standard bootstrap weights in some commercial analytic software can be found in Appendix B.

Bootvar may be downloaded from Statistics Canada's Research Data Centre (RDC) website. Users must accept the Click-Wrap licence before they can read the files. There is a document on the site explaining how to adapt the system to meet users' needs.

#### SAS: <u>http://www.statcan.gc.ca/rdc-cdr/bootvar\_sas-eng.htm</u> SPSS: <u>http://www.statcan.gc.ca/rdc-cdr/bootvar\_spss-eng.htm</u>

#### 8.4 Rounding

In order that estimates produced from the General Social Survey microdata file correspond to those produced by Statistics Canada, users are urged to adhere to the following guidelines regarding the rounding of such estimates. It may be misleading to release unrounded estimates, as they may imply greater precision than actually exists.

#### 8.4.1 Rounding guidelines

1) Estimates of totals in the main body of a statistical table should be rounded to the nearest thousand using the normal rounding technique (see definition in Section 8.4.2).

#### Public Use Microdata File Documentation and User Guide

2) Marginal sub-totals and totals in statistical tables are to be derived from their corresponding unrounded components and then are to be rounded themselves to the nearest thousand units using normal rounding.

3) Averages, proportions, rates and percentages are to be computed from unrounded components and then are to be rounded to one decimal using normal rounding.

4) Sums and differences of aggregates and ratios are to be derived from corresponding unrounded components and then rounded to the nearest thousand units or the nearest one decimal using normal rounding.

5) In instances where, due to technical or other limitations, a different rounding technique is used, resulting in estimates different from Statistics Canada estimates, users are encouraged to note the reason for such differences in the released document.

#### 8.4.2 Normal rounding

In normal rounding, if the first or only digit to be dropped is 0 to 4, the last digit to be retained is not changed. If the first or only digit to be dropped is 5 to 9, the last digit to be retained is raised by one unit. For example, the number 8499 rounded to thousands would be 8000 and the number 8500 rounded to thousands would be 9000.

#### 9. Additional Information

Additional information about this survey can be obtained from the individuals listed below. Data from the survey is available through Statistics Canada's Research Data Centres (RDCs), published reports, special request tabulations. The microdata file will be available from the Social and Aboriginal Statistics Division (SASD) of Statistics Canada. Tabulations can be obtained at a cost that will reflect the resources required to produce the tabulation.

Appendix B - Tips for using GSS standard bootstrap weights in some commercial analytic software

# Tips for using GSS standard bootstrap weights in some commercial analytic software

A survey weight variable with a corresponding set of 500 standard bootstrap weight<sup>1</sup> variables are provided with many GSS data files in order that a full designbased approach may be taken for doing analysis with the data.

A design-based approach to analysis first involves using the survey weight variable for obtaining weighted estimates of the quantities of interest. Then, additional information about the survey design is used in order to make estimates of the variances<sup>2</sup> (and covariances) of these estimated quantities. In the case of many GSS PUMF's, this additional information is in the form of 500 survey bootstrap weight variables. The design-based estimates and variance estimates can then be used for making the inferences required in the analysis.

The form of a bootstrap variance estimate can be described briefly as follows:

Let  $\hat{\beta}$  be the weighted estimate of quantity of interest,  $\beta$ , computed using the survey weight variable w, and let  $\hat{\beta}^{(b)}$  be an estimate obtained <u>in exactly</u> the same manner, except for substituting the *b* th bootstrap weight variable  $w^{(b)}$  for the survey weight variable w, b=1,2,...500. This yields the bootstrap estimates  $\hat{\beta}^{(1)}$ ,...., $\hat{\beta}^{(500)}$  of  $\beta$ . Then the usual bootstrap estimate of the variance of  $\hat{\beta}$  is

$$\hat{V}_{B}(\hat{\beta}) = \frac{1}{500} \sum_{b=1}^{500} \left( \hat{\beta}^{(b)} - \hat{\beta} \right)^{2}.$$
 (1)

If  $\hat{\beta}$  is a vector instead of a single value, such as if  $\hat{\beta}$  is the set of coefficients of a model, then the matrix of estimates of the variances and covariances of the elements of  $\hat{\beta}$  is  $\hat{V}_B(\hat{\beta}) = \frac{1}{500} \sum_{b=1}^{500} (\hat{\beta}^{(b)} - \hat{\beta}) (\hat{\beta}^{(b)} - \hat{\beta})'$ . (The value "500" in the formula is due to the fact that we have 500 different series of bootstrap

the formula is due to the fact that we have 500 different series of bootstrap weights. If the number of bootstrap samples should change from 500, then the values in formula (1) would need to change.)

Survey bootstrapping is just one replication approach that may be used in order to obtain design-based variance estimates with survey data. While several commercial software packages for design-based analysis offer replication approaches for variance estimation, they usually do not specify bootstrapping as one of these approaches. However, due to the similarity in the form of the variance estimate for

<sup>&</sup>lt;sup>1</sup> Unlike previous years, GSS now uses standard bootstrap weights. Special attention should be given to formula (1) as it is different from the formula for the mean bootstrap weights.

 $<sup>^{2}</sup>$  The variance that is estimated in a design-based approach is the variability in an estimate due to resampling by exactly the same design from the same finite population.

the bootstrap and for the particular replication method called BRR, programs that can carry out variance estimation by this latter approach with user-supplied replication weights can be used to obtain bootstrap variance estimates<sup>3</sup>. In particular, in these software, the 500 bootstrap weights provided in the GSS PUMF need to be designated as 500 BRR weights.

In the sections below, instructions will be given for implementing bootstrap variance estimation with GSS PUMF data, using 3 different commercial software packages that can carry out some design-based analysis for BRR: Stata 9 or 10, SUDAAN and WesVar. In all GSS cycles where bootstrap weights are provided, the names given to these bootstrap variables in the user documentation are wtbs\_001 to wtbs\_500<sup>4</sup>. The name of the survey weight variable is usually wght\_per.

## Stata 9 or 10

Beginning with Version 9, the commercial software package Stata added some replication approaches for carrying out design-based variance estimation in its survey analysis commands. One replication approach offered is the BRR approach, and it is this approach that would be specified when analyzing GSS data. In order to specify this approach, the following is recommended:

1. Before using any of the survey analysis commands, use a "svyset" statement to declare the data to be survey data, to designate the variables that contain information about the survey design and to specify the method for variance estimation. Settings made by "svyset" are saved with a dataset when (or if) a dataset is saved. The form of the svyset statement to be used with a GSS analysis dataset would have the following form:

# svyset [pweight=wght\_per], vce(brr) fay(0) brrweight(wtbs\_001-wtbs\_500) mse

Declaring **pweight=wght\_per** tells Stata that the survey weight (which is often called the probability weight) is the variable wght\_per.

The option **vce(brr)** states that the variance estimation approach to use is BRR.

The option **fay(0)** states that the BRR variance estimation approach used does not require a Fay's adjustment. A Fay's adjustment was required when using mean bootstrap weights but, starting with cycle 27 of GSS, we now use standard bootstrap weights and this adjustment is unnecessary.

<sup>&</sup>lt;sup>3</sup> For a more detailed description see Phillips (2004)

<sup>&</sup>lt;sup>4</sup> Please note that in previous GSS cycles (cycle 26 and earlier), the variables wtbs\_001 to wtbs\_500 were mean bootstrap weights. Beginning with Cycle 27 Social Identity, the variables wtbs\_001 to wtbs\_500 are standard bootstrap weights.

The option **brrweight(wtbs\_001-wtbs\_500)** states that the names of the BRR weight variables are **wtbs\_001**, **wtbs\_002**, ..., **wtbs\_500**. This option can also be designated as **brrweight(wtbs\_\*)** provided there are no variables other than the bootstrap weight variables whose names begin with "wtbs\_".

Finally, the **mse** option tells Stata to calculate the variance using squared differences between bootstrap estimates and the full-sample estimate of the quantities of interest, as shown in equation (1). If this option is not included, Stata uses squared differences between each bootstrap estimate and the mean of all the bootstrap estimates. Both approaches should yield approximately the same result.

2. There is an extensive list of survey analysis commands in Stata, which take a design-based approach in their computations. These commands, described in the Stata documentation, are implemented through the use of the "svy" prefix along with the names of other estimators. For example, **svy: mean** is the command for estimating population and subpopulation means and estimates of variability taking a design-based approach. When the **svyset** statement precedes all survey commands, the survey commands do not have to contain any information about the design-based approach to be taken. It should be noted that, even though most of the commands that allow the "svy" prefix are also the names of commands for non-survey data, what is estimated, what options are available and what can be done through post-estimation change when the "svy" prefix is added.

# **SUDAAN**

SUDAAN is a commercial software package developed by the Research Triangle Institute specifically for analysis of data from complex sample surveys and other observational and experimental studies involving cluster-correlated data. The SAScallable version of the software is particularly useful to people familiar with SAS.

Specification of the variance estimation approach to be used by SUDAAN is done in the procedure statement for a particular procedure. Additional sample design statements provide further information required by the program. In particular, to carry out bootstrapping with GSS data, the following is required:

- specify **DESIGN=BRR** in the procedure statement
- include the following WEIGHT statement to identify the survey weight variable:

#### WEIGHT wght\_per;

- include the REPWGT statement to indicate the names of the bootstrap variables on your data file. In particular, for GSS PUMFs, this REPWGT statement would have the form:

#### REPWGT wtbs\_001-wtbs\_500;

## WesVar

WesVar is a software package produced by Westat which carries out various analyses of survey data using exclusively replication methods for variance estimation. One of the methods offered is BRR. Quoting heavily from Phillips (2004), in WesVar, the variance estimation method is specified when creating a new WesVar data file. The resulting file is then used to define workbooks where table and regression requests are carried out. To define a WesVar data file with bootstrap weights:

- Move the replicate weight variables (i.e., wtbs-001 to wtbs\_500) to the *Replicates* box..
- Move the survey weight variable (i.e., wght\_per) to the *Full sample* box.
- For the bootstrap, specify the *Method* as BRR.
- Move analysis variables to the *Variables* box, a unique identifier to the ID box (optional), and save the file.

Appendix D - Content Comparison

Cycle 27 (2013)	Cycle 22 (2008)	Question	Change
RECID	RECID	same	-
AGEGR10	AGEGR10	same	-
SEX	SEX	same	-
MARSTAT	MARSTAT	same	-
HSDSIZEC	HSDSIZEC	same	-
AGEPRGR0	-	new	new variable (age group of partner/spouse)
AGEPRGRD	AGEPRGRDIF	not the same	variable name changed
SEXPR	SEXPR	same	-
PRTYPEC	PRTYPEC	same	-
AGECRYGC	AGECHRYC	not the same	variable name changed
AGEHSDYC	AGEHSDYC	same	-
CHINHSDC	-	new	new derive variable (children in household)
CHH0014C	CHH0014C	same	-
CHRTIME6	CHRTIME6	same	-
PARNUM	PARHSDC	not the same	less detailed response categories
LIVARR06	LIVARR08	not the same	fewer response categories
MULTIGEN	MULTIGEN	same	-
REGION	REGION	same	-
PRCODE	PRV	not the same	variable name changed
LUC RST	LUC RST	same	-
IUM Q10	IUR Q100	not the same	variable name changed
ISM Q10	UR Q115	not the same	variable name changed
ISM Q20	UR Q125	not the same	variable name changed
ISM Q30	UR Q135	not the same	variable name changed
IUY Q01	IUR Q140	not the same	variable name changed
ICR_Q10	-	new	new question (social networking websites)
SOCNET	-	new	new derive variable (social networking websites)
ICR_Q30	-	new	new question (social networking websites)
SCR_Q10	SCR_Q010	not the same	variable name changed
CWR_Q10	SCR_Q120	not the same	variable name changed
CWR_Q20	SCR_Q130	not the same	variable name changed
CWR_Q25	-	new	new question (text messaging)
CWR_Q30	SCR_Q140	not the same	variable name changed
CWR_Q40	SCR_Q150	not the same	variable name changed
CWR_Q45	SCR_Q160	not the same	variable name changed
RFE_Q10C	SCR_Q810	not the same	variable name changed; capped at 200+
RFE_Q20C	SCR_Q820	not the same	variable name changed; capped at 200+
RFE_Q25	SCR_Q830	not the same	variable name changed
SCF_Q100C	SCF_Q100	not the same	variable name changed; capped at 200+
SCF_Q101	SCF_Q101	same	-
SCF_Q102C	SCF_Q102	not the same	variable name changed; capped at 200+
SCF_Q110C	SCF_Q110	not the same	variable name changed; capped at 200+
CWF_Q10	SCF_Q120	not the same	variable name changed

Cycle 27 (2013)	Cycle 22 (2008)	Question	Change
CWF Q20	SCF Q121	not the same	variable name changed
CWF Q30	SCF Q125	not the same	variable name changed
			new derive variable (number of close social
CLSCONGC	-	new	contacts)
CWF_Q40	SCF_Q130	not the same	variable name changed
CWF_Q45	-	new	new question (text messaging)
CWF_Q50	SCF_Q140	not the same	variable name changed
CWF_Q60	SCF_Q150	not the same	variable name changed
CWF_Q65	SCF_Q160	not the same	variable name changed
SCG_Q120	SCG_Q120	same	-
SCG_Q130	SCG_Q130	same	-
SCG_Q150	SCG_Q150	same	-
SCG_Q160	SCG_Q160	same	-
SCG_Q170	SCG_Q170	same	-
SCG_Q180	SCG_Q180	same	-
SCG_Q190	SCG_Q190	same	-
SCG_Q200	SCG_Q200	same	-
SCP_Q110	SCP_Q110	same	-
SCP_Q115	-	new	new question (for respondents who met 1 person)
SCP_Q120C	SCP_Q120C	not the same	capped at 5+
VCG_Q300	VCG_Q300	same	-
VCG_Q310	VCG_Q310	same	-
VCG_Q320	VCG_Q320	same	-
VCG_Q340	VCG_Q340	same	-
CER_Q110	CER_Q110	same	-
CER_Q120	CER_Q111	not the same	variable name changed
CER_Q140	CER_Q112	not the same	variable name changed
CER_Q150	CER_Q113	not the same	variable name changed
CER_Q160	CER_Q114	not the same	variable name changed
CER_Q170	CER_Q115	not the same	variable name changed
CER_Q180	CER_Q116	not the same	variable name changed
CER_Q190	-	new	new question (seniors' group)
CER_Q200	-	new	new question (youth organization)
CER_Q210	-	new	new question (immigrant/ethnic association)
CER_Q230	CER_Q230	same	-
CERD230C	-	new	new derive variable (total number of organization types)
GRP_Q10C	CER_Q150	not the same	variable name changed; capped at 9+
GRP_Q20C	CER_Q160	not the same	variable name changed; capped at 6+
GRP_Q25	CER_Q160	not the same	new question (for respondents with 1 group)

Cycle 27 (2013)	Cycle 22 (2008)	Question	Change
			new question (Internet participation - sharing
GRP_Q30A	-	new	knowledge)
			new question (Internet participation -
GRP_Q30B	-	new	support/advice)
			new question (Internet participation - organizing
GRP_Q30C	-	new	activities)
			new question (Internet participation - office or
GRP_Q30D	-	new	administrative work)
			new question (Internet participation -
GRP_Q30E	-	new	emails/forums)
GRP_Q40	CER_Q170	not the same	variable name changed
OIF_Q10	CER_Q180	not the same	variable name changed
OMA_Q110	OMA_Q110	same	-
IWO_Q10C	OMA_Q115C	not the same	variable name changed; capped at 10+
IWO_Q20	OMA_Q120	not the same	variable name changed
DPO_Q10	OMA_Q125	not the same	variable name changed
DPO_Q20	OMA_Q130	not the same	variable name changed
DPO_Q30	OMA_Q140	not the same	variable name changed
DPO_Q60	OMA_Q170	not the same	variable name changed
